Basis of Report

This document has been prepared by SLR Consulting Limited (SLR) with reasonable skill, care and diligence, and taking account of the timescales and resources devoted to it by agreement with Renewable Energy Systems Ltd. (the Client) as part or all of the services it has been appointed by the Client to carry out. It is subject to the terms and conditions of that appointment.

SLR shall not be liable for the use of or reliance on any information, advice, recommendations and opinions in this document for any purpose by any person other than the Client. Reliance may be granted to a third party only in the event that SLR and the third party have executed a reliance agreement or collateral warranty.

Information reported herein may be based on the interpretation of public domain data collected by SLR, and/or information supplied by the Client and/or its other advisors and associates. These data have been accepted in good faith as being accurate and valid.

The copyright and intellectual property in all drawings, reports, specifications, bills of quantities, calculations and other information set out in this report remain vested in SLR unless the terms of appointment state otherwise.

This document may contain information of a specialised and/or highly technical nature and the Client is advised to seek clarification on any elements which may be unclear to it.

Information, advice, recommendations and opinions in this document should only be relied upon in the context of the whole document and any documents referenced explicitly herein and should then only be used within the context of the appointment.

1.0 Introduction

1.1 General

SLR Consulting Ltd (SLR) was commissioned by Renewable Energy Systems Ltd ("the "Applicant"). to undertake a Peat Landslide Hazard and Risk Assessment (PLHRA) at the proposed Torfichen Wind Farm (the "Proposed Development). The Proposed Development is located within the Midlothian Council Local Authority, approximately 4 km south of Gorebridge. The village settlements of North Middleton and Temple lie approximately 3 km to the north-east and north-west of the site respectively and the larger settlement of Penicuik is located approximately 9.5km to the north-east of the Proposed Development. The location and layout of the Proposed Development are detailed on **Figures 10.1.1 and 10.1.2** respectively with the site defined by the red line boundary.

The Proposed Development would comprise 18 wind turbines with associated infrastructure including access tracks, crane hardstandings, borrow pits, control building and substation, battery storage compound and temporary construction compounds.

The purpose of this report is to consider the extent of peat and potential peat slide hazard within the area of the Proposed Development and consider the potential impact to the Proposed Development, such that areas of deep peat and areas at high risk of a peat slide can be avoided during the design phase.

This report presents the findings of data obtained from peat depth probing surveys conducted by SLR Consulting between September 2022 and July 2023.

The work has been undertaken by a team of Geotechnical Engineers and Geologists, with over 10 years' experience in undertaking peat assessments. The team was led by a Chartered Hydrogeologist with 30 years' consultancy experience and specialising in the assessment of soils, geology and water for renewable power projects in Scotland.

The methods adopted for the assessment follow the best practice guidance¹ issued by the Scottish Government for investigation, assessment and reporting for wind farms in peat areas. Where relevant, reference is also made to guidance published by the Scottish Environment Protection Agency (SEPA) and wind farm construction good practice guidance.

1.2 Background

The importance of assessing the stability of peat deposits in relation to wind farm developments came to the fore as a result of peat failures during the construction of Derrybrien² Wind farm in Ireland in 2003. Although no fatalities were associated with these failures, there was a significant environmental impact. Wind farms tend to be constructed in high moorland areas which are associated with significant peat deposits (typically blanket bogs). There is a potential for peat instability to occur, particularly where deposits are in excess of 1 m thick. Peat instability is influenced by many factors, including, but not limited to, peat thickness, hill slope gradient, underlying geology and subsurface hydrology.

1.3 Scope and Objectives of the Report

The purpose of a report is to identify those parts of the Proposed Development that are naturally susceptible to a higher risk of instability so that they can be avoided or

¹ Peat Landslide Hazard and Risk Assessments (Scottish Government, April 2017)

² Lindsay, R.A. and Bragg, O., (2004), 'Windfarm and Blanket Peat, The Bog Slide of 16th October 2003 at Derrybrien, Co. Galway, Ireland'. University of East London

accommodated. It should be noted that all peat slopes have a risk of instability and the vast majority of peat slope failures occur naturally.

The peat stability assessment is primarily concerned with the influence of the peat on the development of the wind farm. The main objective is to assess the potential peat stability at the Proposed Development, identify areas of potential concern and identify mitigation measures to ensure the maintenance of peat stability before, during and after construction. All aspects of construction should be based on ensuring minimum disruption to the peat areas. The objectives have been achieved by completion of the following:

- a desk-based review of available reports which include geological, hydrological and topographical information;
- Phase 1 peat depth survey undertaken by SLR in September 2022 and January 2023;
- Phase 2 peat depth surveys, undertaken by SLR in July 2023;
- Geomorphological mapping of the Proposed Development to identify the prevailing conditions influencing the potential for, or any evidence of, active, incipient or relict peat instability, including identification of the location and photographic record, as appropriate;
- Reporting on evidence of any active, incipient or relict peat instability, and the potential risk of future instability, describing the likely causes and contributory factors;
- Identification of potential controls to be imposed on the Contractors for the Works to minimise the risk of peat instability occurring at the Proposed Development; and
- Provide recommendations for further work or specific construction methodologies to suit the ground conditions at the Proposed Development to mitigate any unacceptable risk of potential peat instability.

Construction of the development would only increase the risk of peat slope instability if good geotechnical construction practice is ignored, and it is a requirement of all renewable energy developments to follow a very carefully worded and designed Construction and Environmental Management Plan (CEMP) which uses many of the recommendations of the PLHRA.

Without the guidance contained in a Construction Method Statement or CEMP, the following factors would increase the risk of instability:

- construction of access tracks;
- excavation and stockpiling for foundations;
- construction of hardstanding area; and
- blocking of natural drainage, inappropriate new drainage or drainage discharge.

It is important to note that peat instability and the impacts of any instability are not constrained by artificial site or ownership boundaries but by topographic and geomorphologic boundaries. It is therefore important to ensure that the breadth of scope of any assessment adequately covers the areal extent of possible impact.

The risk assessment is based on ground models developed using a Geographical Information System (GIS) specifically for this Proposed Development. A numerical analysis was undertaken in which coefficients were allocated for each of the factors influencing peat stability and their impact on possible receptors.

The conceptual layout of the wind turbines and access routes, the findings from the peat probing, sampling and analysis were used by the design team to optimise the wind turbine layout to avoid or mitigate areas of unacceptable peat slide risk. The layout presented in the drawings represents the final iteration of the wind turbine layout.

This system outlined above was developed in accordance with the guidelines on PLHRA by the Scottish Government¹ for the investigation, assessment, and reporting for wind farms in peat areas. The analysis and interpretation are based upon the results obtained from this process as well as previous experience and the results of case studies elsewhere. Where deviations from this guidance have occurred, this is highlighted and explained in the text.

1.4 Site Description

The Proposed Development is located approximately 4 km south of Gorebridge, in the Midlothian area. The site is located on the northern edge of the Moorfoot Hills and generally slopes in a northerly direction ranging between 490m Above Ordnance Datum (AOD) in the south to an elevation of 230 m AOD in the north. The location and layout of the Proposed Development are detailed on **Figures 10.1.1 and 10.1.2** respectively.

The site is accessed from the south via the B7007. The land use on the site is predominantly rough pasture and cultivated agricultural land.

A working quarry is located within the south of the site adjacent to the B7007. Other man-made features within the site boundary include numerous sheepfolds, dry stone walls and post and wire fences. The site is drained by a series of watercourses including the Black and Latch Burns and their associated tributaries which drain the northern slopes of the escarpment.

A complete description of the Proposed Development for the purposes of the Environmental Impact Assessment (EIA) regulations is provided in EIA Report Volume 1: Chapter 3. The Proposed Development is likely to comprise 18 wind turbines, and associated infrastructure including but not limited to:

- associated turbine foundations and transformers;
- hardstanding areas for erecting cranes at each turbine location;
- series of access tracks and turning heads connecting each turbine;
- underground cables linking the turbines to the grid connection;
- control building and substation;
- battery storage compound;
- temporary construction compound(s); and
- borrow pit(s).

2.0 Desk Based Review

2.1 Topography

Based on the digital terrain model available from the British Geological Society (BGS) Geoindex³, the topography on the Proposed Development consists largely of a gently undulating area at the base of steep slopes. The steep slopes are situated along the southern boundary of the site with the slope trending downwards to the north. The highest elevation within the site boundary is in the south, approximately 490 m AOD, at Mauldsie Hill. The lowest point of elevation is located in the north-east corner of the site at approximately 260 m AOD.

2.2 Geology

2.2.1 Artificial Ground

The published geology indicates that made ground deposits are not present within the site area.

The closest made ground deposits recorded on published geology maps are located approximately 0.48 km to the north of the Proposed Development. This made ground is artificial infilled ground of variable composition.

2.2.2 Superficial Geology

Based on the available BGS mapping data, the main type of superficial deposit underlying the site is Glacial Till (Devensian). This is present throughout the site but predominantly in the centre, south and east.

Pleistocene age Glaciofluvial Deposits are present throughout the site, predominantly in the north, west and south of the site. The Glaciofluvial deposits are comprised of sand and gravel with some finer-grained layers of clay, silt and organic material, deposited as a result of meltwater streams.

Peat is also present on the site. Peat is present in the centre and the west of the site. There is limited peat coverage present in areas of the site with steep gradients.

Superficial deposits are noted as absent on multiple hill tops in the southern areas of the site, indicating that there is exposed bedrock at higher elevations.

The superficial geology mapping across the Proposed Development is presented within Figure 10.1.3.

2.2.3 Bedrock Geology

The published BGS data indicates that the bedrock geology underlying the Proposed Development is predominantly sandstone, siltstone, mudstone and limestone from various formations. The main geological formations are outlined below.

The Inverclyde Group (Lower Carboniferous) is present throughout the site, predominantly in the centre, east and west. This unit is comprised of sandstones containing pedogenic limestone and dolomite nodules, fine-grained carbonate units and mudstones with occasional limestone and dolomite and subordinate siltstone and mudstone units.

The Portpatrick Formation (Ordivician) is another major unit present beneath the site in the south and south-west. This unit is comprised of greywacke and siltstone turbidite successions.

³ British Geological Society (BGS), Geoindex Onshore, Available online at: https://mapapps2.bgs.ac.uk/geoindex/home.html?_ga

The Lower Limestone Formation (Lower Carboniferous) is present in the north of the site and is comprised of repetitive cycles of marine limestone, mudstone, siltstone and sandstone.

The Blackhall Limestone (Lower Carboniferous) underlies areas in the north of the site. This unit is comprised of limestone with interbedded calcareous mudstone and lime mudstone.

The Strathclyde Group (Lower Carboniferous) is a minor group underlying the north-west of the site, comprised of sandstone, siltstone, mudstone with occasional coal seams, ironstones and limestones.

The Limestone Coal Formation (Upper Carboniferous) is a minor unit present in the north of the site. The formation is comprised of sandstone, siltstone, mudstone and coal seams.

There is an unnamed igneous intrusion present in the south-east of the site where the quarry is located. The intrusion is Late Silurian to Early Devonian in age and of an unknown lithology.

The bedrock geology mapping across the Proposed Development is presented within **Figure 10.1.4**.

2.2.4 Structural Geology

The published BGS geological maps of the area indicate there are two major faults present within the site area. One of the faults is in the north of the site, trending NE-SW, and is approximately 16 km in length within the site boundary. The other fault is present in the south of the site, trending NE-SW, and is approximately 13 km in length within the site boundary.

2.3 Coal Mining and Quarrying

The Coal Authority Interactive Map viewer indicates that the north of the site is located within a Coal Mining Reporting area. In addition, near the northern site boundary, there is a Surface Coal Resource Area. The site is not located within a Development High Risk area and there are no mine entries present within the site boundary, however, there are mine entries present in relatively close proximity to the site, with the closest approximately 1.3 km from the northern site boundary.

2.4 Hydrology

There are no major surface water bodies present within the site boundary. The closest surface water body to the site is the Gladhouse Reservoir, located approximately 1km to the northwest of the site. The source and outflow to this Reservoir is the River South Esk, which is generally flowing south to north. The SEPA Water Classification Hub states that overall hydrological status for the Gladhouse Reservoir and the River South Esk is classified as 'poor' and 'heavily modified' account of physical alterations that cannot be addressed without a significant impact on water storage for public drinking water and protected habitats and species.

2.5 Hydrogeology

Information from the BGS Geoindex and Scotland's environment map indicates that the aquifer underlying the site area is Class 2B and a moderately productive aquifer belonging to the Inverclyde Group. This suggests a multi-layered aquifer with flow yielding up to 10 L/s. Flow within the aquifer is predominantly through fractures and other discontinuities. SEPA Water Classification Hub indicates that the site is underlain by two main groundwater bodies: Gladhouse waterbody (ID: 150486) in the centre and south of the site and the Gorebridge waterbody (ID: 150633) in the centre and north of the site. The Gladhouse waterbody is classified as having a 'good' overall status and the Gorebridge waterbody is classified as having a 'poor' overall status, as part of the most recent 2020 data.

2.6 Flooding

According to the SEPA Flood Risk Maps, the Gladhouse Reservoir has an overall 'high' likelihood of flooding, meaning that each year the site area has a 10% chance of river flooding. The River South Esk outflow has an overall 'high' likelihood, with some parts classified as 'medium' likelihood meaning that each year this area has a 0.5% chance of flooding.

Areas of flood risk within the site area are predominantly associated with river bodies and there are sporadic, minor risks for surface water flooding throughout the site. In accordance with the SEPA Flood Maps, the site is not located within any potentially vulnerable areas.

2.7 Environmental Constraints

The Carbon and Peatland Map 2016 as viewed on Scotland's Environment (SE) website records Class 1 peat on located in the central portion of the site.

The Scottish Natural Heritage (SNH) website was consulted to identify whether the site is within an area designated as a site of Special Scientific Interest (SSSI), RAMSAR, Special Protection Area, Special Area of Conservation (SAC), National Nature Reserve, National Park and other environmentally sensitive areas. There are no environmental designations present within the site area. However, approximately 1km to the northwest of the site, the Gladhouse Reservoir is classified as a RAMSAR, Special Protected Area, and a SSSI. This is due to the presence of Pink-footed goose (*Anser Brachyrhynchus*).

2.8 Geomorphology

The main geomorphological features within the Site are provided in **Figure 10.1.5**.

The aerial photographs were used in conjunction with the DTM data for the Proposed Development to identify the main geomorphological features. These were inspected where identified during site visits when more detailed assessment was undertaken.

Aerial photography using google earth was reviewed dating back to 1985 with images from 2002, 2005, 2009, 2010, 2011, 2012 and 2015 to 2023 also used. Interpretation of available aerial photographs was undertaken to assess and identify evidence of historic peat instability.

The main features are detailed in the following sections.

2.8.1 Peat and Erosional Features

From review of aerial imagery, there is no evidence of peat erosional features within the Proposed Development. This was confirmed by on site observations where no significant peat erosional features were identified.

2.8.2 Drainage Channels

Drainage across the Proposed Development is characterised by a network of streams with extensive anthropogenic drainage across the majority of the Proposed Development. This anthropogenic drainage is likely associated with historic draining to generate suitable agricultural grazing land. The large majority of natural drainage channels were located in the west of the Proposed Development. Drainage channels flow into the Gladhouse Reservoir located west of the site.

2.8.3 Forestry

Areas of small forestry blocks are present within the Proposed Development with adjacent areas to the north still being utilised for forestry.

2.8.4 Bedrock

The OS mapping and aerial photography do not indicate exposed bedrock. This is also confirmed by the site visit where exposed bedrock was recorded to be limited.

2.8.5 Extension/Compression Features

There was no evidence visible in the aerial photographs or site walkovers of any extension or compression features in the peat. It was not possible to identify evidence of any significant historic peat failures or slides on the site of the Proposed Development from the aerial photographs.

3.0 Site Work

3.1 Peat Surveys

Peat depth surveys have been undertaken across a number of phases by SLR. The surveys carried out followed best practice guidance for developments on peatland^{4,5}.

Phase 1 peat probing resulted in probing on a 100 m grid to allow for initial assessment of the developable area which was used in preliminary site layout designs. Phase 2 probing saw detailed probing undertaken across the proposed layout, focussing on access tracks, turbine locations and other site infrastructure. The detailed Phase 2 probing was typically undertaken on a 10 m grid on infrastructure and at 50 m spacings on access tracks.

The final design layout was altered after completion of Phase 2 probing which resulted in limited areas of the proposed infrastructure not being probed in accordance with the SG guidance¹. After a review of existing information and relevant mapping it was deemed not necessary to undertake further visits due to the absence of peat within these areas.

Peat is generally defined as an organic soil in excess of 0.5 m, if the soil is less than 0.5m, then it is considered peaty soil. Thin peat was classed as being 0.5 m to 1.5 m thick, with deposits in excess of this being classed as thick peat. The thickness ranges used were intended to reflect the probability of instability associated with both peat slides (in thin peat) and bog slides.

Where surveys were undertaken by SLR, the thickness of the peat was assessed using a graduated peat probe, approximately 6 mm diameter and capable of probing depths of up to 10 m. This was pushed vertically into the peat to refusal and the depth recorded, together with a unique location number and the co-ordinates from a handheld Global Positioning System instrument (GPS). The accuracy of the GPS was quoted as ±2 m, which was considered sufficiently accurate for this survey. All data was uploaded into a GIS database for incorporation into various drawings and analysis assessments.

Where the peat probing met refusal on a hard substrate, the ‘feel’ of the refusal can provide an insight into the nature of the substrate. The following criteria were used to assess material:

- Solid and abrupt refusal – rock;
- Solid but less abrupt refusal with grinding or crunching sound – sand or gravel or weathered rock;
- Rapid and firm refusal – clay; or
- Gradual refusal – dense peat or soft clay.

Where surveys were undertaken by SLR, an assessment of the substrate was made and recorded at each probe hole. For use within this assessment, engineering judgement has been used to assess the substrate at probes undertaken by other parties.

All probing data is presented in Annex A.

3.2 Peat Depth and Extents

The peat depths encountered across the Proposed Development as presented on **Figure 10.1.6 and Figure 10.1.7**. Interpolation of peat depth was undertaken using Inverse Distance

⁴ Scottish Renewables & SEPA (2012) ‘Developments on Peatland Guidance on the Assessment of Peat Volumes, Reuse of Excavated Peat and the Minimisation of Waste’.

⁵ Scottish Natural Heritage (SNH), SEPA, Scottish Government & James Hutton Institute. (2014)‘ Peat Survey Guidance; Developments on Peatland: site Surveys’.

Weighting (IDW). A total of 3,538 peat probes were undertaken across all survey phases, with the results summarised in **Table A** below.

Table A: Peat Probing Results

Peat Thickness (m)	No. of Probes	Percentage (of total probes undertaken on-site)
0 (no peat)	85	2.4
0.01 – 0.49 (peaty soil)	3166	89.5
0.50 – 0.99	51	1.4
1.00 – 1.49	203	5.7
1.50 – 1.99	0	0.0
2.00 – 2.49	19	0.5
2.50 – 2.99	0	0.0
3.00 – 3.49	7	0.2
3.50 – 3.99	0	0.0
> 4.0	7	0.2

The extents of peat at the site are well defined by topography on the site with peat absent on the higher elevations and base of the slopes in the southern and north-eastern area of the site which includes T1, T4, T6 T8, T8, T10, T11, T12, T13, T14, T16, T17, and T18. Peat deposits are present in the flatter areas of slope typically <2 degrees around T2, T7 and T9 in the western and northern area of the site.

3.3 Peat Condition

Peat is described using the von Post⁹ classification. Peat samples were collected by SLR in July 2023, using a peat auger and used to inform interpretations of the peat condition and underlying substrate.

Based on interpretations from probing and peat core samples, the peat within the Proposed Development is predominantly fibrous to pseudo fibrous. There are some localised deposits of shallow peat that generally comprise clayey layers, whilst areas of thicker peat are predominantly fibrous layers.

Based on field descriptions at augering points, most of the shallow peat would be classified as between H2 and H6 in the von Post classification, showing insignificant to moderate decomposition. Peat Core logs and photographs are presented within Annex B.

3.4 Substrate

Where possible, in the SLR investigation, an assessment of the substrate was made, as described previously. From the evidence of the probing and sampling where available, the substrate falls into one of two principal categories:

- Granular (sand and/or gravel/weathered rock), of glacial origin and occasionally interbedded with silty sands;
- Rock, no rock samples were recovered from the probe locations although where exposed, the rock is seen to be metamorphic rock; and

- Limited cohesive horizons were interpreted by the probing and encountered at the base of peat coring. However, it is likely that any cohesive material is weathered silty material at the top of the weathered glacial material.

4.0 Peat Instability

This section reviews the nature of peat and how current and past activities can influence stability. The factors which are likely to influence the potential for peat instability are:

- significant peat depths over impermeable bedrock or minimal soil;
- the presence of slope gradients greater than 4° (approximately) and general topography;
- natural drainage paths;
- evidence of past failures, including soil creep;
- drainage features at the base of slopes which could lead to undercutting;
- forestry plantations and artificial drainage; and
- recent climate patterns.

It should be noted that peat instability is not a recent phenomenon and there is documentary evidence of peat landslides dating back over 500 years⁶. Many landslides that involve peat have no human interference that could be considered as a trigger and this should be borne in mind when considering the susceptibility of a site to potential instability.

4.1 Background Information Regarding Peat

Peat is found in extensive areas in the upland and lowland regions of the UK and is defined as the partly decomposed plant remains that have accumulated in-situ, rather than being deposited by sedimentation. When peat forming plants die, they do not decay completely as their remains become waterlogged due to regular rainfall. The effect of water logging is to exclude air and hence limit the degree of decomposition. Consequently, instead of decaying to carbon dioxide and water, the partially decomposed material is incorporated into the underlying material and the peat ‘grows’ in-situ.

Peat is characterised by low density, high moisture content, high compressibility and low shear strength, all of which are related to the degree of decomposition and hence residual plant fabric and structure. To some extent, it is this structure that affects the retention or expulsion of water in the system and differentiates one peat from another.

Lindsay⁷ defined two main types of peat bog, raised bog and blanket bog, which are prevalent on the west coast of Europe along the Atlantic seaboard. In Britain, the dominant peatland is blanket bog which occurs on the gentle slopes of upland plateaux, ridges and benches and is predominantly supplied with water and nutrients in the form of precipitation. Blanket peat is usually considered to be hydrologically disconnected from the underlying mineral layer.

There are two distinct layers within a peat bog, the upper acrotelm and the lower catotelm. The acrotelm is the fibrous surface to the peat bog⁸, typically less than 0.5 m thick; which exists between the growing bog surface and the lowest position of the water table in dry summers. Below this are various stages of decomposition of the vegetation as it slowly becomes assimilated into the body of the peat.

For geotechnical purposes the degree of decomposition (humification) can be estimated in the field by applying the ‘squeezing test’ proposed by von Post and Grunland⁹. The humification

⁶ Smith, L.T., (Ed) (1910), ‘The literary of John Leland in or about the years 1535-1543.’ Vol.5, Part IX. London: AF Bell and Sons.

⁷ Lindsay, R.A., (1995), ‘Bogs: The ecology, classification and conservation of Ombratrophic Mires.’ Scottish Natural Heritage, Perth.

⁸ Ingram, H.A.P., (1978), ‘Soil layers in mires: function and terminology’. Journal of Soil Science, 29, 224-227.

⁹ Von Post, L. and Grunland, E., (1926), ‘Sodra Sveriges torvillganger 1’ Sveriges Geol. Unders. Avh., C335, 1-127.

value ranges from H1 (no decomposition) to H10 (highly decomposed). The extended system set out by Hobbs¹⁰ provides a means of correlating the types of peat with their physical, chemical and structural properties.

The relative position of the water table within the peat controls the balance between accumulation and decomposition and therefore its stability, hence artificial adjustment of the water table by drainage requires careful consideration.

4.2 Peat Shear Strength

In geotechnical terms, the shear strength of a soil is the physical characteristic that provides stability and coherence to a body of soil. For mineral soils such as clays or sands, such strength is variously given by an inter-particle friction value and cohesion. Depending on whether the mineral soil is predominantly cohesive (clay) or non-cohesive (sand) governs which of the components of strength control the behaviour of the soil.

For peat soils, where the major constituent is organic and there is likely to be little or no mineral component, the geotechnical definition of shear strength does not strictly apply. At present there is no real alternative method for defining the shear strength of peat, therefore the geotechnical definition is generally adopted, in the knowledge that it should be used with great caution.

As noted previously, the acrotelm or near surface peat comprises a tangle of fresh and slightly rotted roots and vegetable fibres. These roots and fibres impart a significant tensile shear strength capacity to the material which provides it with a significant load carrying capacity. The acrotelm is, in effect, a fibre reinforced soil.

In the more decomposed catotelm, the tensile shear strength is reduced as the roots and fibres become more rotted. However, the loss in strength due to decomposition is off-set to a limited degree, by a gain in strength due to the overburden pressure. In geotechnical engineering there is an established relationship for recently deposited soils, between the shear strength of a sample and the thickness of overburden above it.

Consequently, it is almost impossible to predict a shear strength profile in peat and attempts to measure the shear strength using normal geotechnical methods can be misleading. Typical values of shear strength from hand shear vane would be in the range 10-60 kilopascal (kPa) although values over 100 kPa have been recorded in peat elsewhere. The higher strengths are almost certainly the influence of roots or other non-decomposed material. It is believed that the strength of peat should be quoted as a cohesion value as there are few, if any, discrete particles to give the material a significant frictional resistance. It should be noted, however, that any quotation of shear strength for peat should be treated with extreme caution.

4.2.1 Peat Stability – Factors to be Considered

There is considerable observational information relating to debris and peat flows although the actual mechanisms involved in peat instability are not fully understood. The main influences on slope stability are geological, geotechnical, geomorphic, hydrological, topographic, climatic, agricultural and human influences such as drainage and construction activity. Peat is affected to a degree by changes in any of the above list and it is vital to appreciate that changes to the existing equilibrium would affect the level of slope stability during construction and operation of the Development.

Some of the contributory factors to peat instability are summarised below:

- The geographical limits which could be affected by potential instability are not confined to the artificial boundaries imposed by land ownership; landslip occurring above a site

¹⁰ Hobbs, N.B., (1986), 'Mire morphology and the properties and behaviour of some British and foreign peats.' Quarterly Journal of Engineering Geology, London, 19, 7-80.

could affect the Proposed Development and property down slope or downstream of the Proposed Development for several kilometres;

- Agriculture and grazing have a substantial effect on peat areas and this can be compounded in areas that have been managed to improve grazing. Grazing compacts the peat surface reducing the rainwater infiltration and the additional nutrients change the ecological balance of the original peat bog. Agricultural management can include surface drainage and periodic burning, both of which can leave the surface of the peat bare for a period of time resulting in temporary desiccation of the surface. Subsequent wetting of the peat and resumption of peat accumulation results in the former desiccated and possibly ash covered surface being incorporated into the body of the peat which introduces a weak discontinuity in the profile; this in turn becomes another unknown factor in the stability assessment.
- Forestry has a substantial effect on slope stability particularly in the early stages as the creation of a forest involves disruption of the natural equilibrium and drainage of the slopes and the installation of artificial drains by deep ploughing. The construction of access tracks further disrupts the drainage and concentrates groundwater flow into narrow, fast flowing erosive streams. The work by Winter et al¹¹ noted that forest tracks can act to retard or concentrate the down slope flow of water and thus aid its penetration into the slope below. Such a mechanism has been observed at a number of recent landslips that have affected the road network in Scotland.
- Natural Drainage – some of the precipitation falling onto a natural upland peat bog would be absorbed into the low permeability catotelm peat. However, most of the water would run-off as sheet flow through upper, high permeability acrotelm. Thus, the water is transmitted to the lower slopes in a reasonably controlled manner through a range of interconnections that operate at different scales and speed. Failure to understand this and to disrupt the transmission process for the groundwater could result in instability.
- Artificial Drainage - Where artificial drainage has been used to improve the quality of the grazing or to promote forestry it reduces the overall volume of water entering the bog and transfers this water to the edges more rapidly. This can result in ditches and streams becoming enlarged, causing increased erosion and a greater silt burden in the stream water.

4.3 Peat Mass Stability

The principal surface indicator of peat slide potential is cracking of the peat land surface and it is the identification of crack patterns in the field and the attendant causes of the cracking that is fundamental to a peat stability assessment.

Sites that have exhibited natural instability in the past are likely to be more susceptible to future instability during and following construction of a renewable energy development, therefore it is important to identify such instability as part of the Peat Stability Assessment.

4.3.1 Types of Failure

The result of instability in peat is the down-slope mass movement of the material; there are a number of definitions of peat instability which are used to characterise the type of failure. A brief description is given below:

¹¹ Winter, M.R., Macgregor, F. and Shackman, L. (2005a), 'Scottish tracks networks landslide study' Trunk tracks: network management division, published report series. The Scottish Government.

- Bog Bursts or Bog Flows – the emergence of a fluid form of well humified, amorphous peat from the surface of a bog, followed by the settling of the residual peat, in-situ¹²;
- Peat Slides – the failure of the peat at or below the peat/ substratum interface leading to translational sliding of detached blocks of surface vegetation together with the whole underlying peat stratum; and
- Bog Slide – an intermediate form of instability where failure occurs on a surface within the peat mass with rafts of surface vegetation being carried by the movement of a mass of liquid peat.

4.3.2 Bog Bursts

Accounts of bog bursts are generally associated with very wet climates or areas which have received storm rainfall events. Bog bursts can be associated with particularly wet peat landscapes; therefore, it is possible to identify broad regions of a higher susceptibility to these failures. The constraints used to identify the areas of higher susceptibility to bog burst failure are given below:

- peat thickness in excess of 1.5 m with no upper limit;
- shallow gradients, generally within the range of 2 to 10°, peat thicker than 1.5 m is generally not observed on slopes steeper than 10°, also moisture content is generally reduced on steeper slopes due to drainage);
- ground which is annually waterlogged to within the upper 1 m below ground level, (the groundwater level may rise above this but rarely falls below)¹³;
- greater humification of the lower catotelm within the waterlogged ground; and
- lower surface tensile strength of the fibrous peat and vegetation.

The humified mass can be considered as analogous to a heavy liquid and the stability of this mass is maintained by the strength of the surface or acrotelm peat. Should the surface become weakened through erosion or desiccation or the construction of a surface drainage ditch for agricultural or forestry reasons or through turbary (peat cutting), failure is made more likely.

4.3.3 Peat Slides

Peat slides tend to be translational failures with a defined shear surface at or close to the interface with the substrate.

The factors generally considered to influence susceptibility to peat slide failures are listed below:

- peat depth up to 2 m;
- slope gradients between 5° and 15°;
- natural or artificial drainage cut into the surrounding peat landscape;
- greater humification of the lower catotelm within the waterlogged ground; and
- lower surface tensile strength of the fibrous peat and vegetation.

It is noted that some of the factors causing instability are common to both bog bursts and peat slides.

The peat – substrate interface is the primary zone of failure and is enhanced by elevated water content at this boundary and softening or weathering of the lower mineral surface. For this

¹² Dykes, A.P and Kirk, K.J., (2001), 'Initiation of a multiple peat slide on Cuilcagh Mountain, Northern Ireland.' Earth Surface Processes and Landforms, 26, 395-408.

¹³ Crisp, D.T., Dawes, M. & Welch, D. (1964), 'A Pennine Peat Slide', The Geographical Journal, Vol 130, No4, pp519-524.

reason, any investigation or probing should try to distinguish the nature of the lower mineral substrate.

4.3.4 Bog Slides

A bog slide is a variation on a peat slide where part of the peat mass is subject to movement, usually on an internal layer of material, which may be more prone to movement, such as an interface between the acrotelmic and catotelmic layer.

4.3.5 Natural Instability

The stability of a peat mass is maintained by a complex interrelationship of many factors, some of which may not be immediately obvious. Key factors include sloping rock head and proximity to a water body. Rainfall often acts as the trigger after the slope has already been conditioned to fail by natural processes.

It should also be remembered that peat bogs are growing environments and that there would come a time, on sloping ground, where the forces causing instability, the weight of the bog, can no longer be resisted by the internal strength of the peat and its interface with the underlying mineral surface. At this point, failure would occur.

The weight of the peat bog or any soils mantling steep hill slopes would be increased during periods of very heavy rain and it is common to see landslips occurring following extreme rain events. This may be a concern for future developments where one of the predicted effects of global warming will be a greater frequency of extreme weather, intense storms being one element.

5.0 Slope Stability/Ground Conditions

The stability of slopes is dependent upon the shear strength of the soil to resist the disturbing forces due to the weight of the soil, the effects of the groundwater and other disturbing influencing forces.

The level of stability of a slope is normally assessed by reference to the factor of safety which is expressed, numerically, as the degree of confidence that exists, for a given set of conditions, against a particular failure mechanism occurring. It is commonly expressed as the ratio of the load or action which would cause failure against the actual load or actions likely to be applied during service. This is readily determined for some types of analysis (e.g. limit equilibrium slope stability analyses).

5.1 Shear Strength

The strength of the peat in the upper acrotelm is significantly influenced by the root and fibres that are abundant in this layer. There are many influences on the stability of the peat and observing or measuring high shear strength should not be used to assume a high degree of stability.

5.2 Stability Risk Assessment

It is apparent that the stability of peat is complex and the numerous inter-relationships that affect the stability are not fully understood.

A stability risk assessment was undertaken to evaluate the risk of instability occurring associated with the construction of the turbine bases and access tracks at the Proposed Development.

6.0 Peat Landslide Hazard and Risk Assessment

A preliminary peat risk assessment has been undertaken for the Proposed Development. Following several phases of peat probing, a site visit by an experienced SLR geotechnical engineer, and appraisal of the data, the potential for a peat slide occurring at the Proposed Development was initially assessed as low, this was based on the fact that:

- although there are significant thicknesses of peat present on-site, the wind turbines and ancillary infrastructure has generally avoided the thickest areas of peat;
- no evidence of historical or current peat slide activity at the site;
- shallow to moderate gradients ($<8^\circ$) where turbines overlying peat are proposed;
- conclusions of a detailed walkover and results from probing;

Where areas of medium and high risk are identified, further assessment is necessary.

To further quantify this initial assessment, analysis of the terrain at the Proposed Development utilising GIS has been undertaken to analyse slopes and gradients, as shown on **Figure 10.1.8**. The site specific slope data has been combined with site specific peat depth data and using Scottish Government Guidance¹ for the assessment of the risk of instability in peat, an assessment of peat slide risk has been completed.

The method of risk and hazard assessment has been developed with reference to the Scottish Government Guidance¹. Key factors which may have an effect on the stability of the peat deposits have been identified leading to an assessment of the RISK of instability. The potential impact of any instability, the HAZARD, was then considered for identified potential receptors. Scores were attributed to the key factors that have the greatest influence on peat stability. Risk scores were determined, which, when combined with an assessment of vulnerability of potential targets, were developed into an assessment of the hazard.

In order to differentiate between risk and hazard, the following nomenclature has been adopted in Table B.

Table B: Risk vs Hazard

Risk	Hazard
Negligible	Insignificant
Low	Significant
Medium	Substantial
High	Serious

This section outlines the approach taken and the scores allocated for various factors relevant to peat stability.

At this stage in the development, the objective is to determine relationship between peat areas and the Proposed Development and to set out the mitigation that could be adopted and incorporated into the overall development plan to ensure that due cognisance is taken in this regard.

The level of slope is normally assessed by reference to the factor of safety which is expressed, numerically, as the degree of confidence that exists, for a given set of conditions, against a particular failure mechanism occurring. It is commonly expressed as the ratio of the load or action which would cause failure against the actual load or actions likely to be applied during service. This is readily determined for some types of analysis (e.g. limit equilibrium slope

stability analyses). The following sections present a brief discussion on some of the issues relating to stability and risk assessment.

The stability of peat is a complex subject and there are numerous inter-relationships that affect the stability.

A quantitative assessment requires a numerical input and such an analysis cannot account for the unquantifiable input required for a comprehensive peat stability assessment. For this reason, a purely quantitative assessment should only be considered as a guide and a qualitative assessment of stability should be used to inform the final recommendations.

The characteristics of the peat failure phenomena have been incorporated in a stability risk assessment to evaluate the risk of instability occurring within the peat areas. The main factors controlling the stability of the peat mass are the surface gradients, the depth and condition of the peat at each location and the type of substrate.

The natural moisture content and undrained shear strength of the peat are important; however, it is generally accepted that where present, the peat would be saturated and have a very low strength. It is believed to be unrealistic to rely on specific values of shear strength to maintain stability when back analysis of failed slopes indicates that there is often a significant discrepancy between measured strength in peat and stability. Shear strength has been assumed to be constant and worst case, throughout this assessment. It has also been assumed, as a worst case, that the groundwater level is coincident with the ground surface.

The key factors identified as being critical to stability and the development of a risk rating system is:

- Slope gradient;
- Peat thickness;
- Substrate type or condition; and
- Historic instability.

The risk scores are multiplied together to generate a risk rating which is a measure of the likelihood of peat instability.

6.1 Slope Gradients

The slope gradients were assessed by reference to the mapping and particularly the DTM which was used to generate a gradient map (**Figure 10.1.8**), from which the gradient at each probe location could be determined and input into the risk rating spread sheet (Annex A). The gradient quoted at each location was based on the average gradient over a 5 m grid. Significant effort has gone into reducing slopes along routes and at wind turbine bases and positioning infrastructure on flat areas, it is evident from the Slope Plan that the majority of the tracks close to turbines and at turbines are on areas with moderate gradients (<8°). Table C gives the coefficients applied to the categorised slope angles.

Table C: Coefficients for Slope Gradients

Slope Angle (°)	Slope Angle Coefficients
Slope <2°	1
2°≤ Slope <4°	2
4°≤ Slope <8°	4
8°≤ Slope <12°	6
>12° Slope	8

Coefficients for slope gradient have been assigned to ensure the potential for both peat slides (gradients of 4-15°) and bog slides (gradients of 2-10°) are addressed.

By simple inspection it is clear that steeper slopes pose a greater risk of instability than shallow gradients. Therefore, a graduated gradient scale from 0° to >12° (the practical maximum gradient on which peat is commonly observed) has been applied.

6.2 Peat Thickness and Ground Conditions

The ground conditions were assessed by using peat depths recorded during peat probing. Thin peat was classed as being 0.5 m to 1.5 m thick, with deposits in excess of this being classed as thick. The thickness ranges used are intended to reflect the risk of instability associated with both peat slides (in thin peat) and bog slides. Where the probing recorded peat less than 0.5 m thick, this has been considered to be an organic soil rather than peat. **Table D** gives the coefficients applied to the various ground conditions.

In addition to peat thickness, the presence of existing landslip debris or indicators of metastable conditions such as tension cracks or slumping in the peat suggest the material is likely to become even less stable should the existing ground conditions change. Where evidence of historical slips, collapses, creep or flows is seen, a separate coefficient has been applied.

Table D: Coefficients for Peat Thickness and Ground Conditions

Ground Conditions	Ground Condition Coefficients
Peaty or organic soil (<0.5 m)	1
Thin Peat (0.5 – 1.5 m)	2
Thick Peat (>1.5 m)	3*
Slips /collapses / creep / flows	8

*Note that thicker peat generally occurs in areas of shallow gradients and records indicate that thick peat does not generally occur on the steeper gradients.

6.3 Substrate

As noted above, most failures in thin peat layers occur at the interface with the underlying substrate; the nature of the substrate has a very large influence on the probable level of stability.

Where sand and/or gravel (derived from glacial till) form the substrate, the effective strength of the interface can be considered to be good with comparatively high friction values. Under these conditions, failure is likely to occur in a zone within the peat, just above the interface. Further factors are necessary to cause a failure of this nature (increased pore pressures within the peat) and occurrence of such events is rare.

Where clay forms the interface, there is likely to be a significant zone of softening in the clay (due to saturation at low normal stresses, poor or non-existent vertical drainage and the effect of organic acids), resulting in either very low undrained shear strength or low effective shear strength parameters. The result is that potential shearing could occur either in the peat, on the interface or in the clay; all three possibilities have been documented in the past.

A rock substrate provides a high strength stratum, however, the rock surface can be smooth, and, depending on the dip orientation of the strata, it can provide a very weak interface. For these reasons, at this stage, a rock interface has been given the same risk rating as clay. **Table E** gives the coefficients applied to the various substrate descriptions.

Table E: Coefficients for Substrate

Substrate Conditions	Substrate Coefficients
Granular	1
Cohesive	2
Rock	2
Not proven	3
Slip material (Existing materials)	5

If the overall thickness of the peat had not been proven, the risk associated with the significant thickness and the unknown substrate would have been given a high rating to accommodate the unknown factors.

6.4 Risk Rating

The probability of a peat landslide rating coefficient (score) was derived by multiplying the coefficients for the four key factors (with historic instability as 1) identified in the above sections together to produce a risk rating which is a measure of the likelihood of peat instability, and this enables potential areas of concern to be highlighted.

For the stability risk assessment, the following Probability of a Peat Landslide classes were applied as shown in **Table F**.

Table F: Probability of Peat Landslide

Risk Rating Coefficient	Potential Stability Risk (Pre-Mitigation)	Action
<5	Negligible	No mitigation action required.
5 - <15	Low	As for negligible condition plus development of a site-specific construction and management plan for peat areas.
15 - <31	Medium	As for Low condition plus may require mitigation to improve site conditions.
31-50	High	Unacceptable level of risk, the area should be avoided. If unavoidable, detailed investigation and quantitative assessment required to determine stability and sensitivity to minor changes in strength and groundwater regime combined with long term monitoring.
>51	Very High	Unacceptable level of risk, the area should be avoided.

The rating system outlined above differs slightly from that proposed in the Scottish Government Guidance¹ as the system adopted here incorporates three inputs compared to two in the guidance, with the potential impact of substrate added in this section.

The table of results, presented in **Annex A**, indicates peaty soil (<0.5 m) was encountered within 3,251 probe locations and peat (>0.5 m) at 288 locations. The stability risk rating identified the following:

- No peat at 85 probe locations (2%);
- Negligible risk at 3,224 probe locations (91%);
- Low risk at 225 probe locations (6%);
- Medium risk at 4 probe locations (1%); and

- High risk at 0 probe locations (0%).

Figure 10.1.9 presents the interpreted risk of peat instability based on the multiplication of the risk coefficients discussed above in **Table C** to **Table E**.

6.5 Wind Turbines

The peat stability risk rating for each proposed wind turbine is summarised in **Table G**.

Table G: Stability Risk Rating at Each Wind Turbine

Turbine No.	Peat Depth (m)	Substrate	Slope (°)	Stability Risk Rating	Acceptable Location
T1	0.1	Granular	3.2	Negligible	Yes
T2	0.9	Granular	1.9	Negligible	Yes
T3	0.1	Granular	2.3	Negligible	Yes
T4	0.2	Granular	7.2	Negligible	Yes
T5	0.4	Granular	1.8	Negligible	Yes
T6	0.3	Granular	5.0	Negligible	Yes
T7	0.4	Granular	0.2	Negligible	Yes
T8	0.1	Granular	4.5	Negligible	Yes
T9	1.0	Granular	1.4	Negligible	Yes
T10	0.1	Granular	6.3	Negligible	Yes
T11	0.1	Granular	5.4	Negligible	Yes
T12	0.2	Granular	3.3	Negligible	Yes
T13	0.2	Granular	3.9	Negligible	Yes
T14	0.1	Granular	0.5	Negligible	Yes
T15	0.1	Granular	2.5	Negligible	Yes
T16	0.2	Granular	3.4	Negligible	Yes
T17	0.1	Granular	2.3	Negligible	Yes
T18	0.2	Granular	4.0	Negligible	Yes

The distribution of peat is well defined by the multiple phases of probing and based on the absence of peat at T1, T6, T11, T13, T15 and T16, the likelihood of peat stability risk being present at these locations is considered to be low.

6.6 Hardstandings

The peat stability risk rating for each proposed hardstanding is summarised in **Table H**.

Table H: Stability Risk Rating at Each Hardstanding

Turbine Hardstanding No.	Peat Depth (m)	Substrate	Slope (°)	Stability Risk Rating	Acceptable Location
T1	0.4	Granular	1.4	Negligible	Yes
T2	0.3	Granular	1.0	Negligible	Yes

Turbine Hardstanding No.	Peat Depth (m)	Substrate	Slope (°)	Stability Risk Rating	Acceptable Location
T3	0.1	Granular	4.1	Negligible	Yes
T4	0.3	Granular	0.3	Negligible	Yes
T5	0.1	Granular	5.8	Negligible	Yes
T6	0.3	Granular	2.0	Negligible	Yes
T7	0.2	Granular	3.8	Negligible	Yes
T8	0.4	Granular	2.0	Negligible	Yes
T9	0.1	Granular	4.7	Negligible	Yes
T10	0.2	Granular	3.4	Negligible	Yes
T11	0.1	Granular	7.1	Negligible	Yes
T12	0.3	Granular	4.9	Negligible	Yes
T13	0.1	Granular	0.6	Negligible	Yes
T14	0.2	Granular	4.3	Negligible	Yes
T15	0.1	Granular	3.2	Negligible	Yes
T16	0.1	Granular	2.9	Negligible	Yes
T17	0.1	Granular	2.1	Negligible	Yes
T18	0.1	Granular	3.9	Negligible	Yes

6.7 Access Tracks

The results show that all the proposed access track show a negligible or low potential stability risk, as presented on **Figure 10.1.9**.

6.8 Remaining Infrastructure

The peat stability risk rating for each infrastructure element is summarised in **Table I**.

Table I: Stability Risk Rating at Infrastructure

Infrastructure Element	Peat Depth (m)	Substrate	Slope (°)	Stability Risk Rating	Acceptable Location
Proposed Temporary Enabling Works Compound	0.10	Granular	4.41	Negligible	Yes
Proposed Temporary Construction Compound	0.12	Granular	1.90	Negligible	Yes
Proposed Battery Storage Compound	0.16	Granular	1.91	Negligible	Yes
Proposed Control Building and Substation Compound	0.12	Granular	2.83	Negligible	Yes
Proposed Borrow Pit Search Area N	0.12	Granular	2.56	Negligible	Yes
Proposed Borrow Pit Search Area S	0.10	Granular	11.28	Low	Yes

6.9 Hazard Score Development

A further assessment of the medium risk locations has been undertaken. It should be noted that the impact assessment is primarily concerned with impacts that affect the environment, ecology, public or infrastructure associated with the development, both on-site and potentially off-site. These assessments do not consider the detailed ecological impact of construction induced peat instability; however, the majority of the sensitive on-site receptors are the watercourses and thus the inferred ecological and environmental issues are addressed. The proposed mitigation measures in Section 7.0 would limit the potential for any slope failures into water courses and drainage features hence limit such impacts.

The effect a slope failure may have on the construction site and infrastructure can be easily identified. However, the effect of an instability event on features impacted by an event not associated with the Proposed Development is harder to predict.

In order to address this effect, it is not considered appropriate to assess the effect at every potential receptor location close to the Proposed Development; but rather to assess the effect a particular infrastructure feature (track, wind turbine, etc.) would have on the structures or features surrounding it. By adopting such an approach, the assessment of infrastructure features where a risk ranking of ‘negligible’ or ‘low’ (assessed in the stability risk assessments described above) is discounted from further assessment.

6.10 Receptor Ranking

Now the infrastructure features with a ‘medium’ risk rating for instability have been identified it is necessary to identify potential impact receptors. These are nearby structures or features that may be affected by peat movements caused during or following construction. Generally, only receptors immediately down gradient of the infrastructure feature could be affected by peat instability therefore the first phase of feature ranking requires topographic ridges and valleys to be identified across the Proposed Development and surrounding area. From this, receptors at risk from particular infrastructure features can be identified. However, should instability occur on a steep slope, there is the risk of the back scarp of the instability migrating up-slope, there-by affecting areas previously considered not to be at risk.

Following identification of receptors at risk, these are ranked according to their size and sensitivity. **Table J** presents the coefficients placed on particular receptor types.

At the Proposed Development, only watercourses are deemed significant receptors potentially at risk from peat slides. Communities have been discounted due to distance from infrastructure, the impact therefore, should a slide occur is directly to water courses.

Table J: Coefficients for Impact Receptor Ranking

Nature of Feature	Feature Coefficient
Non-critical infrastructure (minor/private roads, tracks)	1
Watercourses and critical infrastructure (pipelines, motorways, dwellings and business properties etc.)	3
Sub-Community (settlement 1-10 residents)	6
Community (settlement of >10 residents)	8

6.11 Receptor Proximity

The proximity of an impact receptor is also critical in assessing the likely level of disruption it may suffer following an instability event. Based on this, two further coefficients – distance from

infrastructure feature and relative elevation differences between the infrastructure feature and impact receptor - are applied in deriving an impact ranking. **Table K** and **Table L** present the coefficients derived for distance and elevation of impact receptors.

Table K: Coefficient for Impact Feature Distance

Distance from Coefficient Feature	Distance Coefficient
> 1 km	1
100 m – <1 km	2
10 – <100 m	3
0 – <10 m	4

Table L: Coefficient for Impact Feature Elevation

Relative Elevation of Feature	Elevation Coefficient
0 -<10 m	1
10 – <50 m	2
50 – <100 m	3
> 100 m	4

6.12 Impact Rating

The impact rating coefficient (score) is derived by multiplying the receptor ranking coefficient (score) by the distance coefficient (score) and the elevation coefficient (score) for each impact receptor associated with a particular infrastructure feature.

Based on distance to impact receptors, in this instance we have identified watercourses (which are the most sensitive receptor near the Proposed Development). The other receptors have been discounted, either they are not present or distance to receptor mitigates risk. Watercourses are the principal receptor as they are at risk of not only direct impact from a peat slide but potentially the water course creates a pathway to impact other receptors indirectly, either ecological or potential water users downstream. Based on **Table J** the watercourses would have an impact receptor coefficient (score) of 3 and then considering the distance to the receptor and the relative elevation differences on-site of receptors, a potential impact can be derived.

6.13 Hazard Ranking

The Scottish Government Guidance¹ recommends that the hazard ranking is assessed using the following formula:

1. Hazard Ranking = Hazard x Exposure

This philosophy can be applied to the assessment carried out so far in the following approach:

2. Hazard Ranking = Risk Rating x Impact Rating

In order to achieve a meaningful and manageable result from the hazard ranking, the results of the Risk Rating and Impact Rating have been normalised to a standard numerical scale (below).

Table M: Rating Normalisation

Risk Rating		Impact Rating	
Current Scale	Normalised Scale	Current Scale	Normalised Scale
Negligible <5	1	Very Low <10	1
Low 5 - <15	2	Low 11 - 20	2
Medium 15 - 30	3	High 21 - 30	3
High 31 - 50	4	Very High 31-50	4
Very High >51	5	Extremely High >51	5

The method of assessing probability of landslide, adverse consequence and hazard developed by SLR Consulting incorporates additional critical elements such as the substrate interface and coefficients for the receptor position, distance and elevation and as such is considered to be more rigorous than the assessment scheme proposed by the Scottish Government¹. The ultimate Hazard Ranking scale does equate to the Scottish Government¹ scale, with hazard rankings divided over four zones.

A simple multiplication of these coefficients would result in potentially large and unwieldy risk and impact rating numbers. SLR has therefore opted to normalise these values to bring them in line with the values used in the Scottish Government Guidance¹, as illustrated in Table N.

Table N: Hazard Ranking

Hazard Ranking	Hazard Ranking Zone	Action
1-4	Insignificant	No mitigation action required although slide management and monitoring shall be employed. Slide management shall include the development of a site specific construction plan for peat areas.
5 - 10	Significant	As for Insignificant condition plus further investigation to refine the assessment combined with detailed quantitative risk assessment to determine appropriate mitigation through relocation or re-design.
11 - 16	Substantial	Consideration of avoiding project development in these areas should be made unless hazard mitigation can be put in place without significant environmental effect.
17-25	Serious	Unacceptable level of hazard; development within the area should be avoided.

6.14 Results

The stability risk assessment has demonstrated that the majority of the Proposed Development lies within an area of negligible to low risk (99% of probe locations) with regards to stability based on **Figure 10.1.9**.

1% of probe location identified a medium risk of peat instability across the Proposed Development. Following review, the majority of these locations are not considered to have either a potential impact on the development infrastructure, due to locality, either well away from influencing infrastructure, in a down gradient position or have no impact on the local watercourses (receptors). Therefore, 1 medium risk location has been identified and is discussed in the following section.

The stability risk assessment results presented in **Table O** shows the calculated hazard ranking associated with every location where there is a stability risk of medium, at or close to infrastructure. The particular mitigation measures to reduce the risk of instability occurring are dependent upon location and the type of proposed structure. Proposed mitigation measures and actions already undertaken to reduce the risk of peat instability occurring are also identified in Table P, together with the associated, revised hazard ranking. A more detailed discussion of the possible mitigation measures is presented in Section 7.0.

6.15 Hazard Rated Locations

As noted in **Figure 10.1.9** and, where the risk assessment has identified a negligible or low risk of peat instability, no specific mitigation measures are necessary. However, in order to ensure best practise is employed, there would be a need for careful monitoring and the construction management must include careful design of both the permanent and temporary works appropriate for peat soils; these are discussed further in Section 7.0.

The areas of the infrastructure that were rated as medium risk, were subjected to a hazard assessment; a number of areas were discounted as they were located off the proposed access track and do not fall within influencing distance of any of the key proposed site infrastructure.

The procedure adopted was to review **Figure 10.1.9** and identify those areas with a medium risk, that were in close proximity or influencing distance of any of the proposed infrastructure or watercourses. Those risk areas where there is no development would not affect the natural stability of the peat.

Although the potential hazards identified in **Table O** can be mitigated to ‘insignificant’ it is believed that hazards should be subject to further post consent investigation and on-going monitoring during construction. Further details of mitigation during construction are described in Section 7.0.

Table O: Stability Hazard Ranking Assessment

Location	Coordinates (E, N)	Risk Rating	Impact Rating	Hazard Ranking	Mitigation	Revised Hazard Ranking
1 (Access track)	332283, 653374	Medium	Low	Significant	Model impacted by localised areas of thin peat (1.2 m) and moderate slope (5°) on access track south of T2. Excavation of localised peat prior to construction would reduce risk and mitigate peat landslide to the north-west.	Insignificant

7.0 Construction Issues and Mitigation Measures

It has been shown that excavation, drainage and general construction activities can have a destabilising influence on peat and that design should allow for the delicate and susceptible condition of the peat. There is no evidence for past peat instability on-site, however appropriate good practice measures and mitigation should be employed to minimise the risk of adverse effects on peat and hydrological receptors.

The following sections highlight the construction issues that should be considered for each general area of construction. Many of the issues raised would be incorporated into the site specific CEMP and construction method statement for the Proposed Development.

The following is a list of controls that should be considered for incorporation into the development of construction methodologies for the works in all areas of peat during detailed design stage:

- Appropriately experienced and qualified engineering geologist/geotechnical engineer is appointed during the construction phase, to provide advice during the setting out, micro-siting and construction phases of the works;
- Geotechnical Risk Register is developed and maintained by the appointed geotechnical engineer;
- A minimisation of “undercutting” of peat slopes, but where this cannot be avoided, a more detailed assessment of the area of concern by the geotechnical engineer would be required;
- Careful micro-siting of wind turbine bases, crane hardstandings and access track alignments to minimise effects on the prevailing hydrology;
- Although the risk of a peat slide is considered to be low for the majority of the development, it is recommended that methodologies should be developed as a contingency to minimise the effects to watercourses in the unlikely event of peat instability; and
- Use of floating track across extensive areas of deep peat if site specific conditions allow.

Notwithstanding any of the above comments, detailed design and construction practices would need to consider the particular ground conditions and the specific works at each location throughout the construction period.

The following list of mitigation measures is provided in an attempt to minimise the risk of potentially inducing peat landslides during construction of the Development.

7.1 General

The following list of mitigation measures is provided in an attempt to minimise the risk of potentially inducing peat landslides during construction of the Proposed Development;

- raise Health and Safety awareness of the peat environment at the proposed Development for construction staff by incorporating the issue into the site Induction. Include peat slide risk assessment information (e.g. peat instability indicators, best practice and emergency procedures) in toolbox talks with relevant operatives e.g. plant drivers;
- introduce a ‘Peat Hazard Emergency Plan’ to provide instructions for site staff in the event of a peat slide or discovery of peat instability indicators;

- for sections of track that require track side cuttings into peat, suitable support measures would need to be designed to maintain the stability of the adjacent peat terrain;
- refine/optimise the design through the pre-construction phase following completion of a detailed ground investigation; and
- develop methodologies to ensure that accelerated degradation and erosion of exposed peat deposits does not occur as the break-up of the peat top mat has significant implications for the morphology, and thus hydrology, of the peat (e.g. minimise off-track plant movements within areas of peat).

7.2 Drainage Measures

Drainage design for the Development is a critical mitigation measure in maintaining the hydrological conditions. In order to maintain hydrological conditions, the following requirements of the drainage measures should be met;

- development of drainage systems that would not create areas of concentrated flow or cause over, or under, saturation of peat habitats;
- development of robust drainage systems that would require minimal maintenance;
- a robust design of drainage systems and associated measures (i.e. silt traps, etc.) to minimise sedimentation into natural watercourses. Method statements should be prepared in advance to mitigate against a slide occurring and should include, but not be limited to, the use of check dams and erosion protection to limit flows and prevent contamination of watercourses; and
- measures shall be put in place to ensure drainage systems are well maintained, to include the identification and demarcation of zones of sensitive drainage or hydrology in areas of construction, e.g. inclusion of maintenance regimes for drainage systems into a construction management plan or similar.

7.3 Construction Recommendations

A summary of recommendations for site specific infrastructure is provided in the following sections.

The complexity of peat stability has been discussed in this report and by Lindsay and Bragg², amongst others. Following a review of published work and the observation and analysis undertaken for the development, there would be a negligible hazard from peat instability if the recommendations contained in this report are adopted.

Suitable guidance and documentation in the form of a construction method statement/CEMP would be established before work commences to ensure good construction practices. Due to the complex inter-reactions affecting peat stability it is proposed that the recommendations given below are used as a set of guidelines to generate a detailed design concept. The concept should include the range of potential risks discussed in this report and the design should be sufficiently flexible to allow for continual modification and up-dating as construction progresses.

7.3.1 Wind Turbine Locations and Crane Pads

It is proposed that construction of the wind turbine foundations will require excavation of peat and subsoil to create a suitable area for the foundation of the base.

In general, the bearing stresses imposed by a wind turbine are relatively low and the main requirement of the base is to resist the overturning moments generated by the wind acting on

the turbine. Gravity base foundations are designed to control bearing pressures to a level appropriate to the local ground conditions and provide stability against turbine loading.

The excavations for wind turbine bases and crane pads should be kept to a minimum where possible but it is likely that the required hard stratum would be typically several metres deep, beneath soft materials (peat), unless directly on rock. The very soft nature of peat means that unsupported cut or excavated slopes could be unstable unless shallow gradients are used. The overall width of such an excavation would be around 33 m diameter at the original ground surface, depending on the thickness of the peaty soil/peat and glacial till and appropriate methods of stabilising the temporary slopes should be considered. Foundation excavation would produce large volumes of peat and this should be reused across the Proposed Development in an environmentally acceptable manner for restoration. Peat would not be used to back fill the excavation void within the footprint of the foundation as it would have a very low strength. Peat could be used as backfill outside the foundation footprint and also to dress verges to tracks and around wind turbine bases, in line with current Waste Management guidance¹⁴ and the Peat Management Plan provided in **Technical Appendix 10.2**.

Management of the water in the peat, by maintaining existing drainage during excavation is essential to avoid creating conditions likely to increase the risk of a peat slide.

7.3.2 Borrow Pits

The proposed borrow pits would be required to comply with appropriate construction and quarrying regulations. They have been deliberately sited to avoid excavating peat and no significant construction mitigation would be required. Should blasting of rock be required during excavation, it is not likely to increase the likelihood of a peat slide as the borrow pits have been proposed in locations with limited peat.

7.3.3 Access Tracks

The general principles regarding the construction of the access tracks in peat that minimises the risk of instability and environmental effects are discussed below.

In order to maintain the current level or improve the stability of the peat mass on the slopes around the access track, it is necessary to ensure that the construction methods do not seriously disrupt the established drainage and that no areas are surcharged, either by water discharge or spoil.

Wherever possible, the following principles should be adopted:

- maintenance of existing drainage is critical, therefore all existing drainage tracks must be maintained and where necessary, channelled below the proposed track construction. Upslope side drainage ditches to the track would be required on side-long ground; the ditches should be constructed with small dams and cross drains where necessary so that water can pass below the track at regular intervals;
- scour and erosion is avoided in the side ditches due the limited volume and velocity, concentrated discharges to the peat on the down slope side of the track are avoided;
- the camber of the track should encourage surface water to drain to the up-slope side drainage ditch;
- track gradients to be maintained at the recommended gradients from the wind turbine supplier, typically shallower than 1 v : 8 h to facilitate access by the large specialist vehicles for both construction and transport of the wind turbine components. The

¹⁴ Scottish Renewables and SEPA (2012). Developments on Peatland: Guidance on the Assessment of Peat Volumes, Reuse of Excavated Peat and the Minimisation of Waste.

maximum acceptable gradients are usually defined by the appointed wind turbine manufacturer.

- identify and mark all existing drainage features within the access track corridors; these drainage features should be maintained (not enhanced) during the construction and operational phases of the development;
- install cross drains at regular intervals to maintain interstitial groundwater flow through the peat mass below the tracks where track settlement could reduce the natural permeability;
- install additional drainage in areas up-slope to any track to prevent ponding and possible instability;
- install small dams at regular intervals along the track side drains to prevent significant water velocities in the side drains causing deep erosion in the peat;
- where track construction is required over extensive peat areas in excess of 1 m deep, this may be undertaken with a floating track construction, where the integrity of the peat allows; and
- cut and fill should be avoided in peat greater than 1 m deep if possible; if not, the following requirements on side long ground (across contours) should be adopted:
 - excavate to a sound stratum;
 - the majority of construction surface's to be essentially horizontal with a slight fall to aid drainage;
 - where the depth of cut is deemed unstable, employ a stepped or benched surface with the intention of minimising the exposed surface of the up-slope cut face;
 - protect all exposed peat surfaces from erosion and desiccation, by ensuring the integrity and moisture content of the peat is maintained; and
 - the top of cut slopes should be provided with a small bund to retain the peat to prevent desiccation and maintain the local stability of the peat.

7.3.4 Watercourses Crossing

The access tracks will cross existing watercourses at a number of locations and care would be required to ensure conformity in the settlement characteristics between the crossing structure and the approaches to avoid undue settlement. The preferred option for the stream crossings will be with the use of culverts and bridges. The larger watercourse crossings will not be influenced by peat. Watercourse crossing designs will be subject to the approval of SEPA.

8.0 Conclusion

The report has highlighted the complicated inter-relationship between all the aspects that have an effect on the stability of peat. Consequently, the discussion has also addressed areas of construction and drainage in order to avoid a stability problem rather than attempt to put it right after the event. The Proposed Development has been assessed for potential hazards associated with peat instability; the assessment has been based on:

- A walk-over survey by an experienced geotechnical engineer;
- A thorough inspection of the digital terrain map;
- Review of historical and geological maps and publications and aerial photography; and
- A detailed geotechnical probing exercise at 3,538 locations in areas of identified peaty soil/peat to determine the thickness thereof.

The overall conclusion regarding peat stability is that there are minimal areas of medium risk of peat instability across the Proposed Development and most have these have been avoided during the design process. For the single medium risk area, a hazard impact assessment was completed which concluded that, with the employment of appropriate mitigation measures, it can be considered as an insignificant risk.

Additional mitigation measures have been identified in areas where hazards are already considered insignificant to further reduce the risk of potential hazards occurring.

The Proposed Development can be considered to have localised areas of thick peat which have been avoided through layout design.

This report should be considered as the first stage in the development of a fundamental understanding of the various inter-relationships that govern and control the peat lands at the Proposed Development.

Good construction methods and appropriate micro-siting would also be effective at controlling residual peat landslide risk for lower risk locations at the site. Providing that the recommended mitigation measures are put in place and adhered to, the risk of peat landslide as a result of the Proposed Development is not significant.

More detailed ground investigations will be required to facilitate the geotechnical design of the various foundations and access track, particularly the vertical and horizontal alignment and the design of the river/stream crossings. These will be incorporated into the Construction Method Statement which will be submitted to the Planning Authority for approval as part of the condition compliance prior to any site works commencing.

It is not the purpose of this report to provide a detailed scope for the investigation; however, it is believed that the strength and stiffness parameters are needed for turbine design and regular probes along access tracks to determine bearing capacity for either excavated or floated track design.

Annex C Peat Coring Data

Technical Appendix 10.1: Peat Landslide Hazard and Risk Assessment

Torfichen Wind Farm

Renewable Energy Services Ltd.

SLR Project No.: 405.064791.00001

26 September 2023

Peat Core Log

Hole No.

PC01

Sheet 1 of 1

Project: Torfichen Wind Farm		Client: RES						Dates: 27-07-2023			
Project No: 405.064791.00001			Logger: CR		Approved By:		Coordinates: E: 332258.00 N: 653405.00				
Location: Borders			Hole Type: PC		Level:		Vertical Scale: 1:26				
Water	Depth (m)	Sample Type	Depth	Recovery (%)	Depth (m) / Discontinuity Detail	Level (mAOD)	Legend	Stratum Description			
	0.00 - 1.00							Light brown fibrous PEAT. Frequent fragments of plant remains throughout (H3), (B2).			
	1	C	0.00 - 1.00	Recovery = 100%	1.00			Brown fibrous PEAT. Frequent fragments of plant remains throughout (H4), (B2).			
	1.00 - 2.00				1.20			Brown pseudo-fibrous PEAT (H5), (B2).			
	2	C	1.00 - 2.00		1.80			Dark brown pseudo-fibrous PEAT. Occasional fragments of plant remains throughout (H6), (B3).			
	2.00 - 2.20	C	2.00 - 2.20		2.10			Grey clayey coarse to fine SAND.			
	3				2.20			Peat Core Complete at 2.20m			
	4										
	5										

Remarks:

Peat core recovered using peat sampler.
